14. Hazard and risk

This assessment considers the key hazards and risks that may arise from the construction and operation of the proposed Western Sydney Airport.

The analysis was based on a review of relevant project documentation including a number of studies conducted for the EIS and local and international aircraft safety data, a conceptual airspace risk model and a series of workshops with key project stakeholders.

Many aspects of the airport design are preliminary and a number of important considerations will only be resolved close to the commencement of operations. While this may be the case, certification of the aerodrome by the Civil Aviation Safety Authority will be required before operations can commence, as well as implementation of the requirements of the existing regulatory framework. Satisfying these regulatory requirements will necessitate detailed design studies.

Based on the design information currently available, no insurmountable risks associated with the proposed Stage 1 airport development are considered likely. Key issues that need to be finalised prior to the operation of the proposed airport include:

- resolution of potential offsite risks associated with jet fuel storage;
- reservation of a pipeline corridor to secure future fuel supply by means other than road transport;
- additional bird and bat surveys to confirm the preliminary low risk identified to date;
- completion of a study to identify stack emissions in the proposed airspace; and
- implementation of development controls on public safety zones outside Commonwealth land.

Prior to operations commencing at the airport, a safety review would need to be undertaken in accordance with the requirements of the applicable work, health and safety legislation.

14.1. Introduction

As part of the development of this environmental impact statement, a hazard and risk review of the Western Sydney Airport proposal was undertaken (refer to Volume 4, Appendix H).

The assessment of key risks associated with the construction and operation of the proposed airport adopted a precautionary approach, consistent with the provisions of the Work Health and Safety Act 2011 (Cth) and Work, Health and Safety Act 2011 (NSW). Due to the preliminary nature of the design, including indicative flight tracks and limited other relevant airspace and terminal design information, a comprehensive due diligence assessment of the proposed airport was not possible.

A review was therefore considered appropriate for the purposes of the EIS, given that a safety assessment to demonstrate due diligence in accordance with WHS legislation would be required before the start of Stage 1 operations. This chapter draws on that study and other work by the Australian Government agencies (such as Airservices Australia), as described in Chapter 7.
14.2. Methodology

The study methodology comprised:

- documentation review – including the findings of the 1997–99 EIS risk study, current project design documentation, and national and international aviation safety statistics;
- legislative context – to establish the legislative context for the proposed airspace and ground operations at the proposed airport;
- development of a conceptual airspace risk model – to provide a framework for a systematic process to identify possible hazards and risks; and
- stakeholder workshops – to discuss identified risks and seek expert opinion on these and any other risks and treatments that should be considered for the proposed airport.

14.2.1. Document review

A number of background documents were reviewed as part of the hazard and risk assessment process, including:

- Western Sydney Airport: Preliminary Airspace Management Analysis (Airservices Australia 2015);
- Western Sydney Airport Climatological Review (Bureau of Meteorology 2015a);
- Western Sydney Airport Usability Report – Meteorological Impacts (Bureau of Meteorology 2015b); and
- Western Sydney Airport indicative airport layouts.

14.2.2. Legislative context

The following Commonwealth legislation applies to airports and aviation:

- Civil Aviation Act 1988;
- Civil Aviation Regulations 1988;
- Civil Aviation Safety Regulations 1998;
- Air Navigation Act 1920;
- Airspace Regulations 2007;
- Airports Act 1996;
- Airports (Protection of Airspace) Regulations 1996;
- Air Navigation Regulations 1947;
- Airport (Building Control) Regulations 1996;
- Airport (Environment Protection) Regulations 1997;
• Airports Regulations 1997;
• Airports (Control of On-Airports Activities) Regulations 1997;
• Airports (Ownership and Interests in Shares) Regulations 1996;
• Aviation Transport Security Act 2004; and
• Aviation Transport Security Regulations 2005.

The Civil Aviation Safety Authority (CASA) has primary responsibility for the safety regulation of civil air operations in Australia. The Civil Aviation Regulations 1988 and the Civil Aviation Safety Regulations 1998 provide the general regulatory controls for the safety of air navigation. The regulations empower CASA to issue Manuals of Standards with detailed technical material, which support the regulations. The following Manuals of Standards are relevant to the proposed Western Sydney Airport:

• Manual of Standards Part 139 – Aerodromes;
• Manual of Standards Part 139H – Standards Applicable to the Provision of Aerodrome Rescue and Fire Fighting Services;
• Manual of Standards Part 172 – Air Traffic Services;
• Manual of Standards Part 171 – Aeronautical Telecommunication and Radio Navigation Services; and

Prior to the proposed airport commencing operations, CASA would need to be satisfied that appropriate operating procedures, and necessary infrastructure and personnel are in place to ensure the safety of aircraft operations in accordance with the Civil Aviation Act and the CASRs. Aircraft operations around the proposed airport would be controlled by the range of aviation-specific Commonwealth Acts and Regulations outlined above.

14.2.2.1. Airspace protection

The airspace at and around airports is protected under Part 12 of the Airports Act and the Airports (Protection of Airspace) Regulations 1996 (APAR). The protected airspace is defined using international standards as the space above two sets of operational surfaces above the ground around an airport, namely the:

• Obstacle limitation surface (OLS); and
• Procedures for Air Navigation Services – Aircraft Operations (PANS-OPS) surfaces.

The OLS is intended to provide protection for aircraft flying into or out of the airport when the pilot is flying by sight. The PANS-OPS surfaces are intended to safeguard an aircraft from collision with obstacles when the aircraft’s flight may be guided solely by instruments, in conditions of reduced visibility.
The Airports Act defines any activity resulting in an intrusion into an airport's prescribed airspace to be a 'controlled activity', and requires that controlled activities cannot be carried out without approval. The APAR provide for the Secretary of the Department Infrastructure and Regional Development to assess and approve applications to carry out controlled activities, and to impose conditions of approval. A controlled activity which results in an intrusion into the airspace above the OLS may be permitted if assessed as acceptable by CASA. CASA may require the approved obstacle to be marked and/or lit.

Long term intrusions into the airspace above a PANS-OPS surface are not permitted as these have a direct impact on the safety of aircraft flying an instrument approach or departure procedure. Buildings and other structures are considered to be controlled activities within the meaning of the Airports Act and the APAR and are dealt with accordingly.

14.2.2.2. Control of development in the vicinity of airports

The National Airports Safeguarding Framework (NASF) is a national land use planning framework, agreed to by Commonwealth, State and Territory Ministers in 2012. The NASF recognises that responsibility for land use planning rests with State and local governments, but that a national approach can assist in improving planning outcomes on and near airports and flight paths.

The NASF guidelines provide comprehensive information and recommendations relating to six airport safeguarding matters. The NASF guidelines are:

- Guideline A: Measures for Managing Impacts of Aircraft Noise;
- Guideline B: Managing the Risk of Building Generated Windshear and Turbulence at Airports;
- Guideline C: Managing the Risk of Wildlife Strikes in the Vicinity of Airports;
- Guideline D: Managing the Risk of Wind Turbine Farms as Physical Obstacles to Air Navigation;
- Guideline E: Managing the Risk of Distractions to Pilots from Lighting in the Vicinity of Airports; and
- Guideline F: Managing the Risk of Intrusions into the Protected Airspace of Airports.

Additional guidelines for the protection of public safety zones and communication, navigation and surveillance infrastructure are proposed to be developed by National Airports Safeguarding Advisory Group in the near future.

The assessment of proposed development in the vicinity of airports is primarily the responsibility of local government, based on declared airspace arrangements. Once the airspace has been declared for the proposed airport, surrounding councils would be notified and OLS and PANS-OPS requirements would be incorporated into local planning instruments. Development with the potential to exceed the OLS must be referred to the airport operator and the Department of Infrastructure and Regional Development for review prior to development proceeding. The OLS applies to both building obstacles (e.g. antennae, masts or tall buildings) as well as hot or high velocity air emissions which may cause a potential hazard to aircraft. In addition to OLS, civil aviation regulations also require approval from CASA for the installation of lighting which might cause a distraction, glare or confusion for pilots.
14.2.2.3. Dangerous goods

There is specific legislation related to the management of dangerous goods. For the storage and handling of dangerous goods (which includes jet fuel), the responsible authority in NSW is WorkCover. Australian Standard AS 1940-2004 – The storage and handling of flammable and combustible liquids deals with flammable liquids of dangerous goods classified as Class 3 substances (flammable liquids) in the UN Recommendations on the Transport of Dangerous Goods – Model Regulations. The objective of AS 1940-2004 is to promote the safety of persons and property where flammable or combustible liquids are stored or handled, by providing requirements and recommendations that are based on industry best practices.

The authority with regard for the transport of dangerous goods is the NSW Environment Protection Authority (EPA) under the provisions of the Dangerous Goods (Road and Rail Transport) Act 2008 (NSW). The approval authority for a fuel pipeline would be the NSW Department of Trade and Investment (Resources and Energy) under the provisions of the Pipelines Act 1967 (NSW).

14.2.2.4. Hazardous industries

The NSW Department of Planning and Environment also provides guidelines for the planning and development of hazardous industry in NSW which applies to land outside of the airport site. Relevant guidelines include the NSW Hazardous Industry Planning and Advisory Paper (HIPAP) series of guidelines:

- HIPAP 4 – Risk Criteria for Land Use Safety Planning (January 2011); and

14.2.3. Conceptual airspace risk model

In conceptual terms, the airport airspace risk analysis approach considers risks in three parts: the entry (arrival and landing), exit (departure and take-off) and transit through the relevant airport airspace. There are a number of factors that add complexity to an airport airspace, including:

- terrain and weather;
- the number and variety of airspace activities;
- multiple runway operations (where applicable);
- possible airspaces resulting in increased traffic density;
- potential runway intrusions including animals;
- public and other environmentally sensitive facilities and activities adjacent to the airport that may affect operations (e.g. population centres, especially schools and hospitals);
- speed differentials between aircraft at the airport; and
- pilot experience differentials.

These issues were tested in stakeholder workshops in order to systematically consider possible airspace risks at the proposed airport and identify, in a preliminary manner, existing regulatory and potential other risk treatments.
14.2.4. Stakeholder workshops

Workshops with representative key stakeholders were completed to identify credible risk issues that should be addressed by the hazard and risk assessment. Workshops or meetings were undertaken with the following stakeholders:

- Department of Infrastructure and Regional Development;
- Civil Aviation Safety Authority, Office of Airspace Regulation;
- Airservices Australia;
- NSW Department of Planning and Environment;
- Australia Federal Police; and
- NSW Rural Fire Service.

14.3. Identified key risks

The risk review process identified a list of key credible hazards that were the subject of analysis and discussion with stakeholders. These can be broadly considered as either airspace or ground-based risks and are outlined in Table 14–1. It should be noted that while each of these risks has a different likelihood of occurrence, they were identified on the basis that each could potentially result in either injury or loss of life to members of the public, airport workers or airline staff.

Table 14–1 – Identified key risks

</tbody>
</table>

For the purposes of the hazard and risk assessment process, these risks were considered separately, as they may have different causes, and mitigation measures would be specific to each risk. For the purposes of the summary below, they have been grouped into broad categories for more general discussion.
14.4. Airspace risk overview

Australia has a good aviation safety record, comparable to other developed countries such as the United States, Canada and the United Kingdom. Statistics collected by the Australian Transport Safety Bureau (ATSB) indicate that the number of reported safety incidents in Australia has risen significantly over the past decade. However, not all incidents result in a physical accident and the growth in incidents reported needs to be considered in light of the continuing increase in aircraft movements. In 2013, among 3.3 million departures of high capacity public transport aircraft, there were 23 serious incidents (occurrences nearly leading to an accident) and two accidents in which serious injury or damage to an aircraft or person occurred.

The 23 aircraft involved in serious incidents in 2013 was the highest rate for this operation type in more than 10 years (ATSB 2014). The most common occurrences reported were wildlife strikes, adverse weather and aircraft system problems. Most accidents and serious incidents involved reduced aircraft separation distance, engine malfunction, or runway excursions.

No fatalities involving high capacity commercial aircraft operations similar to the type proposed at Western Sydney Airport have occurred since 1975 and the number of reported fatal accidents and fatalities declined significantly between 1990 and 2005 to a level considered to be very low (ATSB 2006a).

14.4.1. Flight tracks

Indicative flight tracks have been developed by Airservices Australia for use in the EIS. The indicative design demonstrates that in 2030, it would be possible to independently manage the operations of Sydney Airport and the proposed airport. The indicative airspace design did not consider potential noise or other environmental considerations. A future formal airspace design process is expected to be undertaken closer to the commencement of operations at the proposed airport. Chapter 7 provides further detail on the indicative flight path design, however it is noted that these flight tracks would avoid key infrastructure locations such as Defence Establishment Orchard Hills, the Warragamba Dam wall and Prospect Reservoir.

Commencement of operations of the second runway at the proposed airport would introduce additional complexity to airspace arrangements. Current analysis suggests that a broader reconfiguration of the Sydney Basin airspace would likely be required. However, changes in land and improved navigation technology over time would have some influence over the extent of future reconfigurations.

Similar to the indicative Stage 1 flight paths, a rigorous process of airspace design and approval would need to be undertaken prior to commissioning of a second runway. This two runway scenario at the proposed airport is discussed in Chapter 34.
14.4.2. Navigation systems and air traffic management procedures

A variety of satellite and ground-based navigational aids would provide necessary safety for aircraft approaches and departures in reduced visibility conditions. The required accuracy, operation and availability of these facilities are strictly controlled under the CASR. All aircraft that would operate at the proposed airport in reduced visibility conditions would need to be suitably equipped to use the available navigational aids. Radar services would assist air traffic control to manage air traffic in the controlled airspace surrounding the proposed airport under the CASR.

A satellite assisted precision landing system, known as a ground based augmentation system (GBAS) is proposed for the airport. The system uses GPS signals to provide aircraft with very precise positioning guidance during the final stages of an approach and landing. Airservices Australia and ICAO recognise GBAS as a potential future replacement for current instrument landing systems and adoption of this technology is considered to be a critical component of next-generation air traffic management infrastructure. Each GBAS can precisely guide up to 26 approach flight paths simultaneously from up to 42 kilometres from the runway. The proposed airport would likely include two GBAS – one for each runway.

Another example of emerging technology in the aviation sector is the adoption of automatic dependent surveillance-broadcast for all instrument flight rules (IFR) aircraft. This system allows aircraft to broadcast their position, velocity and other flight details in real time for flight tracking. The technology is being rolled out in the Sydney basin. It is anticipated that the proposed airport would similarly adopt emerging technology and that future incidents would decrease.

As discussed in Chapter 7, the indicative airspace design includes adoption of a ‘point merge’ for aircraft approaches. The point merge method of sequencing arriving traffic was introduced in Norway in 2011 and has been gaining popularity in European and Asian airports such as Seoul and Kuala Lumpur. One of the cited benefits of this new concept is safety improvements through a reduction of tactical vectoring, increased situational awareness in pilots and a lower workload for air traffic control staff.

14.4.3. Bat and bird strike

Birds are attracted to large, open grassed areas which are often found on airports. Such areas provide feeding, resting and nesting areas for many types of birds. Short grass provides protection against predators such as snakes, cats and foxes but may also attract predatory birds in search of rodents and other food sources. Water lying in drains and dams on the airport site may also provide suitable habitat for ibis and ducks. Large open hangars and other flat roofed buildings can also provide nesting areas for small birds.

The environment surrounding airports can also attract birds. These may be natural habitat areas (e.g. wetlands) or urban features such as landfills. Birds and flying foxes can transit across airports and flight paths while travelling between nesting, roosting and feeding sites.

Modern aircraft engines are designed to deal with bird or bat strike. The key issue is the size and flocking habits of the species in and around an airport. While in the worst case bird or bat strike can lead to serious aircraft incidents, the more likely consequence is damage to aircraft and inconvenience to the travelling public.
A preliminary bird and bat strike report (refer to Appendix I) identifies the type and number of species that would likely to be in the vicinity of the proposed airport. It concludes that, unlike many other Australian airports that are situated in coastal areas where birds are more likely to exist, the risk at the proposed airport is comparably low. A range of standard activities and procedures throughout the design, construction and operational phases are would be undertaken to confirm the preliminary results and reduce the areas for potential habitats of various species before airport operations begin. This would include measures to be adopted both on- and off-site, in accordance with the requirements of applicable regulations such as NASF, CASA Advisory Circular 139-26(0) and ICAO requirements.

14.4.4. Airspace obstructions

Airspace obstructions and distractions (e.g. lighting and glare) can be a threat to navigation, but these are controlled through CASA standards and guidelines and through development control assessments of local developments.

A preliminary survey for obstacles in the proposed airport is being conducted to identify any necessary changes to surrounding areas. It should be noted that not all identified obstacles may need to be removed or demolished. Depending on the level of risk posed to aircraft operations, other options such as notifying pilots may be an acceptable resolution. Typical obstructions may include radio masts and transmission towers as well as natural features.

Another type of hazard is hot air discharges such as industrial emissions (stack discharge). Emissions above certain velocities, or chimneys above specified heights, are considered potential hazards in accordance with the Airports (Protection of Airspace) Regulations 1996.

Before the start of airport operations, a survey would be required to identify existing industrial emissions that may pose a hazard to aircraft. Any future industrial developments within the declared airspace would need to be referred to the Department of Infrastructure and Regional Development and the airport-lessee company for comment prior to the development proceeding.

14.4.5. Adverse meteorology

In aviation terms, adverse meteorology refers to the following conditions:

- aircraft icing (freezing fog);
- crosswind (especially gusts);
- cyclones/tornadoes;
- fog (visibility);
- lightning (thunderstorm); and
- windshear (especially in the vicinity of the runway threshold).
The likely occurrence of these meteorological conditions at the airport site was investigated by the Bureau of Meteorology (refer Appendix D) and the outcomes are summarised in Chapter 7. No unusual conditions are likely to exist at the site that would routinely interfere with safe operation at the proposed airport site. A site automatic weather station would collect a comprehensive baseline of local weather conditions before the start of operations to support further analysis. Provided that appropriate airport operating parameters are established and complied with, operational safety concerns associated with adverse meteorology at the airport would be satisfactorily managed.

14.4.6. Aircraft accidents

Australia has a good aviation safety record, comparable to other developed countries. No fatalities involving high capacity commercial aircraft operations similar to the type proposed at Western Sydney Airport have occurred since 1975, and the number of reported fatal accidents and fatalities declined significantly between 1990 and 2005 to a level considered to be very low (ATSB 2006a).

The Civil Aviation Safety Authority (CASA) recently completed an aeronautical study of the airspace arrangements in the Sydney Basin within 45 nautical miles of Sydney Airport. One of the findings of the report was that the Sydney Basin has shown a decreasing rate of total airspace related incidents over the past six years. Most incidents related to airspace involved operational non-compliance or navigation problems resulting in airspace infringements by visual flight rule (VFR) aircraft and did not result in significant safety hazards. This supports the overall findings of the ATSB review.

Aircraft accidents involving multiple fatalities are a rare occurrence in Australia and worldwide (ATSB 2006b). Figure 14–1 provides a summary of commercial jet aeroplane operations between 1959 and 2013 and indicates that over the 54 years of analysis, the annual fatal accident rate has reduced from 40 (1959) to less than 0.5 (2013) per million departures (Boeing 2014).

![Figure 14–1 – Summary of annual fatal accident rate between 1959 and 2013.](image-url)
Figure 14–2 summarises the percentage of fatal accidents by stage of flight which indicates that:

- 10 per cent are likely to occur on the ground during taxiing, loading/unloading, when the plane is being parked or towed;
- 14 per cent are during take-off or initial climb to cruising altitude;
- 10 per cent are during level flight at cruising altitude;
- 11 per cent are during descent and on initial approach to landing; and
- 47 per cent are during final approach or landing.

ICAO reports that most aircraft crashes occur within 1,000 metres of landing and 500 metres of take-off (ICAO 2014). The Australian Government is working with the states and territory governments on the development of a national standard for public safety zones (PSZ) to be incorporated into the NASF. PSZ are areas of land at the ends of runways within which development may be restricted in order to control the number of people on the ground at risk of injury or death in the event of an aircraft accident on take-off or landing. While Australia has an excellent aviation safety record there will always be an inherent risk associated with flying and operation of aircraft at or around airports. The use of PSZs can further reduce the already low risk of an air transport accident affecting people near airport runways. In the absence of any nationally agreed guidance, a nominal 1,000 metre trapezoid-shaped clearance off the end of the proposed runway threshold has been provided in the 2030 airport concept.

An estimate of the likely risk of plane crashes resulting from the proposed airport has been undertaken based on the most recent year of accident data available. In 2013, Boeing reported five major accidents occurred worldwide in their fleet as a result of 25 million departures that year. This equates to an accident likelihood of $2 \times 10^{-7}$ per departure. Table 14–2 shows the likelihood of an accident for the proposed Stage 1 development based on forecast total annual air traffic movements and the 2013 accident statistics.
Table 14–2 – Predicted likelihood of an accident for Stage 1 airport development

<table>
<thead>
<tr>
<th>Total annual air traffic movements (passenger and freight)</th>
<th>Departures (per year)</th>
<th>Likelihood of major accident per departure</th>
<th>Major accidents per year</th>
<th>Years between major accidents</th>
<th>Years between major accidents on final approach or runway</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage 1 (2030)</td>
<td>63,000</td>
<td>31,500</td>
<td>0.0000002</td>
<td>0.0063</td>
<td>159</td>
</tr>
</tbody>
</table>

As indicated in the table, the accident rate for aircraft operating at the proposed Western Sydney Airport in 2030 would be in the order of 1 in 150 years for all stages of flight. It should be noted that this estimate is based on forecast air traffic movements at the airport and an accident rate based on current aviation technology and practices around the world. As outlined in Section 1.4.2, aviation procedures and technology are continually improving, particularly in response to ongoing incident investigations, and therefore it is likely that improved safety performance would be achieved over time.

14.4.7. Terrorism

At this preliminary design stage, no specific issues or precautions beyond those in use at Sydney Airport or other similar international facilities are envisaged for the proposed airport. The detailed design of the proposed airport facilities would be reviewed by security experts to ensure that adequate space for security facilities and personnel is provided and additionally, that the design minimises potential vulnerabilities. Terrorism response considerations could include including provision of aircraft stand-off bays.

14.5. Ground based issues

14.5.1. Transport of dangerous goods

It is expected that jet fuel would initially be transported to the airport site by B-double road tankers to the airport site. In 2030 (approximately five years after opening), the expected fuel demand would require approximately 43 B-double fuel deliveries per day. This number of deliveries would continue to rise in line with the increased aircraft movements at the airport.

It is not currently possible to identify what traffic routes are likely to be used for fuel deliveries, although it is expected the majority of the trip would be by high capacity, arterial roads or motorways, and locally via the M7 and future M12 motorway. This is not a large number of trucks, relative to road capacity or existing heavy vehicle volumes.
At a future point, likely before the operation of the second runway, a fuel supply pipeline would replace the need for supply by a large numbers of road tankers. A route for a fuel pipeline will be determined by the entity or organisation responsible for providing fuel to the airport. Arrangements for access to the fuel pipeline, which may involve an easement, would be required along the pipeline corridor alignment to ensure maintenance access and as a public safety measure. This may include planning controls restricting development on, and adjacent to, the pipeline.

14.5.2. Fuel storage and other fires

The concept design for jet fuel storage as part of the Stage 1 development includes four by 2.5 megalitre storage tanks in a two-by-two configuration, each within a 100 by 100 metre bunded area near the northern boundary of the site. The current buffer from the closest tank to the airport site perimeter is approximately 80 metres.

For the purposes of investigating potential off-site risks resulting from a fire in the fuel storage area, a worst case scenario was assessed involving ignition of a 100 by 100 metre bunded area of jet fuel was considered in conjunction with 20 knot winds blowing towards off-site areas. Based on meteorological investigations, winds exceeding 20 knots are rare at Badgerys Creek (BOM 2015a).

A fire dynamics simulation model for a kerosene fire with 20 knot winds was undertaken and the results shown in Figure 14–3. The vertical coloured bar on the right hand side indicates the different heat flux levels resulting at different distances from the fire.

**Figure 14–3 – Fire dynamic simulation model for a kerosene fire with 20 knot winds**
HIPAP 4 (Department of Planning and Environment 2011a) outlines the potential consequences of varying levels of heat flux on structures and people, noting that the ultimate effect would depend on the duration of exposure. In general terms, buildings should be located outside of a heat flux level of 12.6 kilowatts per square metre which is the point at which timber can ignite after prolonged heat exposure and insulated steel can buckle. Buildings outside the 2.1 kW/m² heat flux level would not typically require special fire protection measures to be adopted.

The preliminary fire modelling shows that a buffer of at least 50 metres is required from the edge of the storage bund to all airport site boundaries would be required to avoid a heat flux level of 12.6 kW/m². The current conceptual design of the fuel storage facility at the proposed airport would satisfy this requirement by incorporating an 80 metre buffer to the site boundary.

The land use zoning of property neighbouring the fuel storage allows for the development of residential dwellings. In consideration of potential injury to people in these locations, HIPAP 4 specifies a heat flux level of 4.7 kilowatts per square metre. This level is considered high enough to trigger the possibility of injury for people who are exposed for more than 30 seconds and are unable to be evacuated or seek shelter.

As shown in Figure 14–3, this heat flux level would only be achieved within approximately 75 metres from the edge of the storage bund and also with the 80 metre buffer provided to the site boundary. Accordingly, it considered that the HIPAP 4 risk criteria are satisfied.

Other fires associated with tanker truck discharge, fires in terminal buildings or other areas or aircraft are also possible, but would likely to be smaller. Standard design precautions would be adopted for all infrastructure. Also, an aviation rescue fire-fighting station is proposed for the Stage 1 development. A mutual aid agreement with the NSW Rural Fire Service would also be in place before airport operations commence.

14.5.3. Flooding

The potential for flooding at the proposed airport is assessed in detail in Chapter 18 of the EIS. The concept design for the proposed airport includes a drainage strategy for the site. The airport infrastructure is located outside the 100 year average recurrence interval flood extent of Badgerys Creek, Duncans Creek and Oaky Creek. The existing creeks on the airport site would be removed and replaced with an extensive stormwater drainage network including a series of detention basins which would be created during the construction stage and remain in use during airport operation.

The airport infrastructure has been designed in accordance with the *Stormwater Drainage Design Manual*, which identifies standards for aerodromes and is consistent with current industry practice. The manual sets minimum flood immunity requirements for airport infrastructure as shown in Table 14–3. Consideration has also been given to *Australian Rainfall and Runoff* (Engineers Australia 1987) recommendations, including the need to make appropriate allowances in the design for blockage of stormwater structures.

The table shows that, for key infrastructure such as runways and taxiways, flood immunity would be required at least a 50 year ARI event, with additional restrictions on the duration for which any water can pond nearby.
During construction, the effects of changes to the site topography would be mitigated by a network of flood detention basins. A detailed surface water management plan would be developed to manage the impacts of on-site flooding during the construction period.

14.5.4. Railway safety

The Stage 1 Development does not currently include a rail service because the recently approved road network upgrades have been assessed as adequate to support anticipated airport demand for at least a decade after opening. Depending on the alignment and preferred timing to develop rail services, some enabling work may be required during the proposed Stage 1 development to future-proof the corridor. Any such work is expected to be subject to a separate approval process.

Underground trains and stations have special safety and operational considerations which would be taken into account in the railway design and approvals process. Railway safety is managed by independent regulators at both the State and Federal levels working in partnership to improve rail safety.

14.5.5. Bushfire

A bushfire risk assessment was conducted as part of the design development of the proposed airport. The proposed airport would be a significant commercial asset, located in a landscape that contains vegetation and landscape features that may represent a bushfire risk.

The most likely scenario for fire at the airport site would be from a large grass fire starting to the west of the site under hot, dry north-westerly, westerly or south-westerly winds. Construction and operation of the proposed airport also has the potential to provide sources of ignition that, under adverse winds, could allow a fire to escape off site.

A Bushfire Management Plan is being prepared for the site to manage current bushfire risk. A revised plan would be prepared for the construction and operation of the airport and would contain procedures for how site personnel should respond in the event of a bushfire occurring within or threatening the site. The plans would be prepared in consultation with the NSW Rural Fire Service.
14.5.6. Contaminated land

A preliminary contamination assessment was conducted during the preparation of the EIS. The scope of work included a desktop study of available documentation, a limited site inspection and preparation of a preliminary conceptual site model which facilitated classification of the site into broad risk categories. Information available for the desktop review included aerial photography, council land zoning, searches of regulatory databases, and information from previous environmental reports and details from a contamination register maintained by the Department of Infrastructure and Regional Development.

The site has historically comprised a variety of land uses including rural residential, agricultural, poultry farming and light commercial activities. These uses can potentially result in contamination including asbestos, scrap metal, agricultural chemicals and fuel storage.

Mitigation measures included priority actions for the further assessment and management of asbestos and lead based paint in identified high risk areas. Before the start of construction, an unexpected finds protocol would be prepared that would detail measures to be undertaken to safeguard potential risks to workers and the environment if contamination not previously recorded is encountered.

14.6. Mitigation and management measures

While a number of potential risk issues were identified and analysed by the hazards and risk study, the majority:

- could be satisfactorily resolved through further design and regulatory processes or studies already underway;
- would not require the adoption of project-specific measures or measures that are not already required by existing industry legislation and standards; or
- would be the responsibility of other statutory authorities to implement, in consultation with the Department of Infrastructure and Regional Development and the future airport lessee company.
These issues and the responsible parties are summarised in Table 14–4.

</table>
| Airservices Australia             | Future formal flight path design process                  | • avoidance of military and emergency services operations from surrounding airfields, existing airspace obstacles, surrounding critical infrastructure and site-specific meteorology; and  
• consideration of possible future, long term flight paths associated with the proposed second runway so that changes in surrounding land use over the intervening period can be appropriately managed. |
| Civil Aviation Safety Authority   | Safe operation of aircraft                                | • aerodrome certification of the proposed airport facilities and equipment are in accordance with the applicable standards and operating procedures make satisfactory provision for the safety of aircraft operations;  
• regulation of drone and model aircraft; and  
• specification of new technology/procedures as demonstrated to be effective. |
| Airport lessee company             | Appropriate design and safe operation of the proposed airport and facilities | • preparation of an aerodrome manual;  
• installation and operation of automatic weather station in consultation with the Bureau of Meteorology;  
• compliance/adoption of new technology/procedures specified by CASA;  
• detailed design of the proposed airport and facilities in accordance with industry standards and regulations e.g. terminal, railway and fuel storage;  
• provision of necessary safety and contingency procedures and facilities in accordance with guidelines;  
• ongoing management of wildlife at the airport in accordance with CASA Manuals of Standards and operational management plan;  
• preparation of an airport master plan in accordance with the Airports Act;  
• participate in planning coordination forums and community aviation consultation groups; and  
• conduct a risk and safety study prior to Stage 1 operations in accordance with the requirements of WHS legislation. |
| Aircraft manufacturers and airline operators | Fuel exhaustion, Mechanical failure, Pilot error, Inflight fire | • continuous improvement and response to identified issues |
| Local councils                     | Airspace intrusion                                        | • refer potential conflicts to the airport-lessee company and Department of Infrastructure and Regional Development. |
The key remaining issues to be resolved in future design stages are provided in Table 14–5.

| 14.3| Bird and bat strike    | Develop a Wildlife Hazard Management Plan to include:  
  - conduct of additional surveys to study and monitor for changes in species and movement patterns. The surveys would be conducted in accordance with relevant Commonwealth and State guidelines and standards including any recovery plans for threatened species;  
  - review of detailed design documentation to identify potential bird and bat attractants; and  
  - liaise with local government in relation to plans for proposed developments within 13 kilometres of the airport site that are likely to increase the bird and bat strike risk. | Pre-operation |
| 14.4| Bird and bat strike    | The outcomes of bird and bat strike monitoring would be reviewed by a wildlife strike expert and the results taken into account in any audit of the airport’s impacts on wildlife in and around the airport site                                                                                                                                   | Operation    |
| 14.5| Public safety zones    | Consider whether any planning measures are required for areas not currently Commonwealth-owned.                                                                                                                                                                                                                                                              | Pre-construction |

### 14.7. Conclusion

At this preliminary design stage for the proposed Western Sydney Airport, adequate precautions have been identified to resolve safety and risk issues. Ongoing design processes would further consider these issues and future regulatory approvals would also need to be achieved before operations could commence. This would include the future formal airspace design process by Airservices Australia, the detailed design of the airport in accordance with the approved Airport Plan (including any conditions in the Airport Plan arising out of the EIS and made by the Minister for the Environment) and the aerodrome certificate from CASA.

The recommended mitigation measures would reduce hazards and risk during construction and operation of the airport, both for airspace and ground based activities.
